# Lecture 25

Greedy Algorithms: Huffman Encoding & its Time Complexity, Activity Scheduling

# Huffman Encoding: Definition

- Huffman Coding is a lossless data compression algorithm. The idea is to assign variable-length codes to input characters, lengths of the assigned codes are based on the frequencies of corresponding characters.
- The most frequent character gets the smallest code and the least frequent character gets the largest code.

# Huffman Encoding

- Huffman Coding is a famous Greedy Algorithm.
- It is used for the lossless compression of data.
- It uses variable length encoding.
- It assigns variable length code to all the characters.
- The code length of a character depends on how frequently it occurs in the given text.
- The character which occurs most frequently gets the smallest code.
- The character which occurs least frequently gets the largest code.
- It is also known as **Huffman Encoding**.

# Huffman Encoding

## › Prefix Rule

- Huffman Coding implements a rule known as a prefix rule.
- This is to prevent the ambiguities while decoding.
- It ensures that the code assigned to any character is not a prefix of the code assigned to any other character.

## › Major Steps in Huffman Coding

- There are two major steps in Huffman Coding-
  - › Building a Huffman Tree from the input characters.
  - › Assigning code to the characters by traversing the Huffman Tree.

# Huffman Encoding: Important Steps

- › The steps involved in the construction of Huffman Tree are as follows-
- › **Step-01:**
  - Create a leaf node for each character of the text.-
  - Leaf node of a character contains the occurring frequency of that character.
- › **Step-02:**
  - Arrange all the nodes in increasing order of their frequency value.
- › **Step-03:**
  - Considering the first two nodes having minimum frequency,
  - Create a new internal node.
  - The frequency of this new node is the sum of frequency of those two nodes.
  - Make the first node as a left child and the other node as a right child of the newly created node.
- › **Step-04:**
  - Keep repeating Step-02 and Step-03 until all the nodes form a single tree.
  - The tree finally obtained is the desired Huffman Tree.

# Huffman Encoding: Important Formulas

(1) Average code length per character = 
$$\frac{\sum (\text{frequency}_i \times \text{code length}_i)}{\sum \text{frequency}_i}$$
$$= \sum (\text{probability}_i \times \text{code length}_i)$$

(2) Total number of bits in Huffman encoded message  
= Total number of characters in the message x Average code length per character  
=  $\sum (\text{frequency}_i \times \text{Code length}_i)$

# Huffman Encoding: Problem

- › A file contains the following characters with the frequencies as shown. If Huffman Coding is used for data compression, determine-
- Huffman Code for each character
  - Average code length
  - Length of Huffman encoded message (in bits)

| Characters | Frequencies |
|------------|-------------|
| a          | 10          |
| e          | 15          |
| i          | 12          |
| o          | 3           |
| u          | 4           |
| s          | 13          |
| t          | 1           |

# Solution

› Construct the Huffman Tree

## Rule

- If you assign weight '0' to the left edges, then assign weight '1' to the right edges.
- If you assign weight '1' to the left edges, then assign weight '0' to the right edges.
- After assigning weight to all the edges, the modified Huffman Tree is- **NEXT SLIDE**

To write Huffman Code for any character, traverse the Huffman Tree from root node to the leaf node of that character.

Following this rule, the Huffman Code for each character is-

- a = 111
- e = 10
- i = 00
- o = 11001
- u = 1101
- s = 01
- t = 11000

From here, we can observe-

- Characters occurring less frequently in the text are assigned the larger code.
- Characters occurring more frequently in the text are assigned the smaller code.

## Average Code Length

- › Using (1), we have **Average code length**
- $$\begin{aligned} &= \sum (\text{frequency}_i \times \text{code length}_i) / \sum (\text{frequency}_i) \\ &= \{ (10 \times 3) + (15 \times 2) + (12 \times 2) + (3 \times 5) + (4 \times 4) + (13 \times 2) + (1 \times 5) \} / (10 + 15 + 12 + 3 + 4 + 13 + 1) \\ &= 2.52 \end{aligned}$$

## Length of Huffman Encoded Message

- › Using (2), we have **Total number of bits in Huffman encoded message**
  - = Total number of characters in the message x Average code length per character
  - =  $58 \times 2.52$
  - = 146.16
  - $\cong 147$  bits

## Example

- › Build the Huffman coding tree for the message

*This is his message*

- › Character frequencies

| A | G | M | T | E | H | _ | I | S |
|---|---|---|---|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 2 | 2 | 3 | 3 | 5 |

- › Begin with forest of single trees

# Example based Simulation

► Message- BCCABBDDAECCBBAEDDCC

Length-20

| Letter | ASCII Code | Binary Form |
|--------|------------|-------------|
| A      | 65         | 01000001    |
| B      | 66         | 01000010    |
| C      | 67         | 01000011    |
| D      | 68         | 01000100    |
| E      | 69         | 01000101    |

In Electric components the alphabet is sent through ASCII code . The ASCII code letter capital A is 65 and we need 8 bis binary to convert 65.

- For 1 Letter We need 8 bits
- For 20 Letters We need  $8 \times 20 = 160$  bits

# Simulation

Message : BCCABBDDECCBBAEDDCC

First of all place the counts in increasing order then take minimum and add them now the root node of letter E and A is 5

| Letter | Count |
|--------|-------|
| A      | 3     |
| B      | 5     |
| C      | 6     |
| D      | 4     |
| E      | 2     |

# Simulation

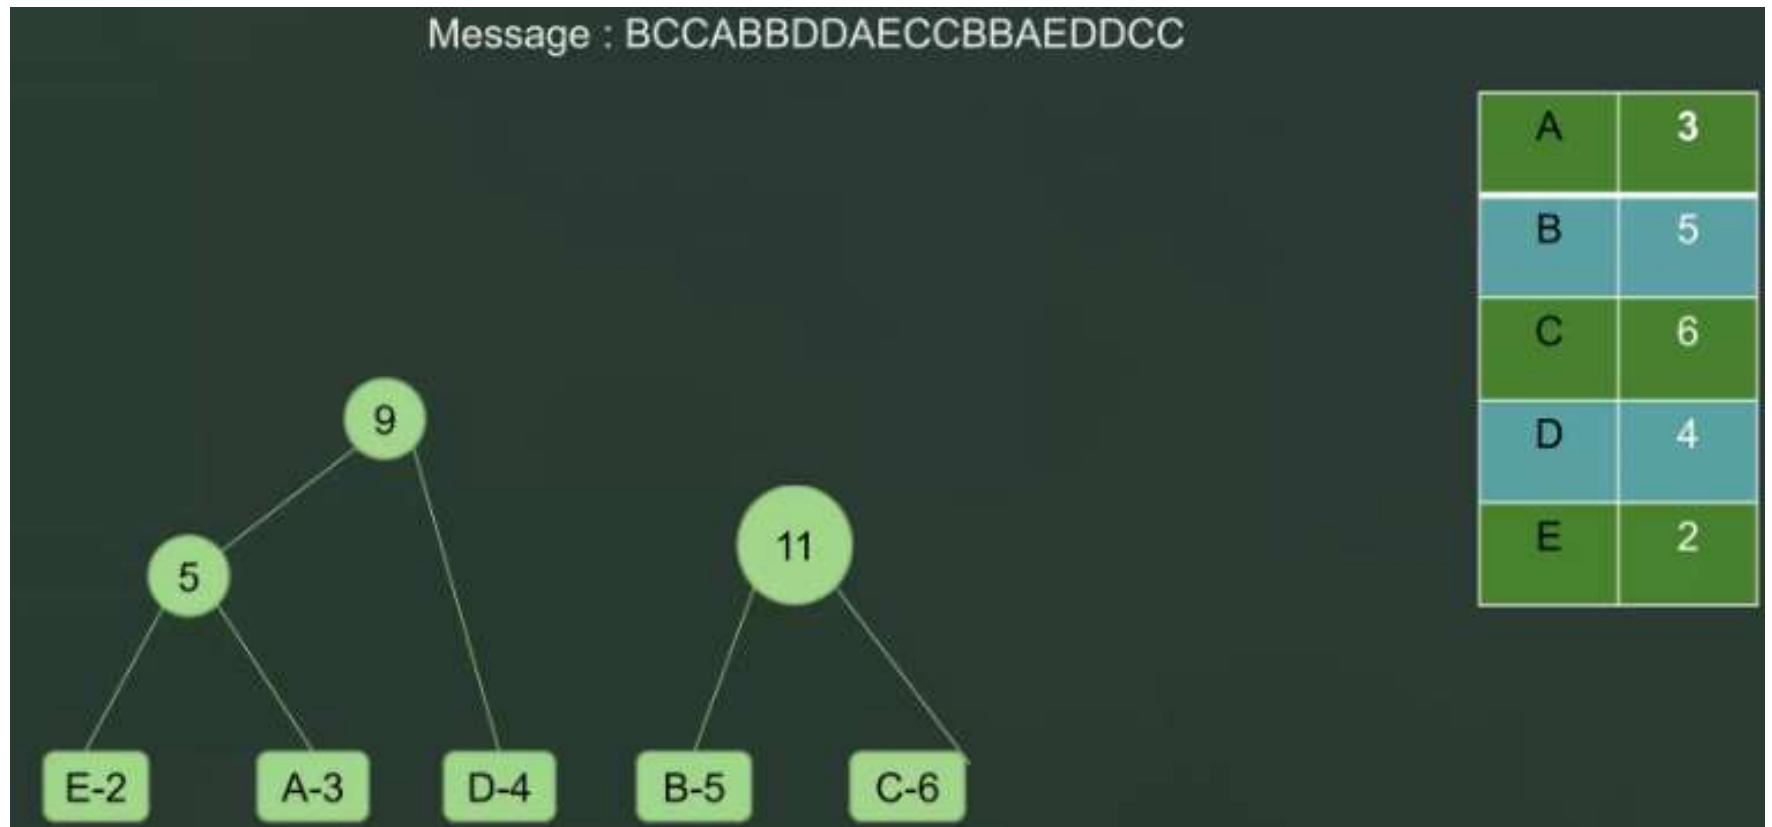

Message : BCCABBDDAECCBBAEDDCC

Then between the root node 5 and counts take the minimum and add them up . Here 5 and 4 are minimum so we add them and make 9 as root node so continue the process.

|   |   |
|---|---|
| A | 3 |
| B | 5 |
| C | 6 |
| D | 4 |
| E | 2 |

# Simulation

# Simulation

Message : BCCABBDDAECCBBAEDDCC

# Simulation

Message : BCCABBDDAECCBBAEDDCC

Mark the left hand edges as 0 and right hand edges as 1 and then traverse from root node to any letter . Suppose we want to go A from root node so the distance will be 001, for B 10 and so on.

# Simulation

Message : BCCABBDDAECCBBAEDDCC

For A we need 3  
bits , B 2 bits , C 2  
bits , D 2 bits, E 3  
bits

For A,  
Count =3  
So total bits  $3 \times 3 = 9$  bits  
And so on

|   |     |
|---|-----|
| A | 001 |
| B | 10  |
| C | 11  |
| D | 01  |
| E | 000 |

# Simulation

Message : BCCABBDDECCBBAEDDCC

|   |   |     |                   |
|---|---|-----|-------------------|
| A | 3 | 001 | $3 \times 3 = 9$  |
| B | 5 | 10  | $5 \times 2 = 10$ |
| C | 6 | 11  | $6 \times 2 = 12$ |
| D | 4 | 01  | $4 \times 2 = 8$  |
| E | 2 | 000 | $2 \times 3 = 6$  |

Total=45 bits

As we see first we do need 160 bits and now we need 45 bits now we have compressed the cost and size.

# Algorithm

procedure Huffman( $X, f(\cdot)$ )  $X$  is the set of symbols, whose frequencies are known in advance  
 $n = |X|$ , the number of characters  
for all  $x \in X$ , enqueue( $(x, f(x))$ ,  $Q$ )  $Q$  is a min-priority queue, implemented as binary-heap  
for  $i = 1$  to  $n - 1$   
    allocate a new tree node  $z$   
     $left\_child = \text{deletemin}(Q)$   
     $right\_child = \text{deletemin}(Q)$   
     $f(z) = f(left\_child) + f(right\_child)$   
    Make  $left\_child$  and  $right\_child$  the children of  $z$   
    enqueue( $(z, f(z))$ ,  $Q$ )

# Complexity of Algorithm

procedure Huffman( $X, f(\cdot)$ ) Thus, the algorithm needs  $O(n \log n)$   
 $n = |X|$ , the number of characters  
 for all  $x \in X$ , enqueue( $(x, f(x)), Q$ ) needs  $O(n \log n)$   
 for  $i = 1$  to  $n - 1$  Thus, the loop needs  $O(n \log n)$   
     allocate a new tree node  $z$   
      $left\_child = \text{deletemin}(Q)$  needs  $O(\log n)$   
      $right\_child = \text{deletemin}(Q)$  needs  $O(\log n)$   
      $f(z) = f(left\_child) + f(right\_child)$   
     Make  $left\_child$  and  $right\_child$  the children of  $z$   
     enqueue( $(z, f(z)), Q$ ) needs  $O(\log n)$

## Pseudo-code

```

Huffman (C)
n = |C|
Q = C
for i = 1 to n-1
    allocate new node z
    z.left = x = Extract-min (Q)
    z.right = y = Extract-min (Q)
    insert (Q, z)
return Extract-Min (Q) // returns the root
    
```

Time complexity of Huffman Coding is  $O(n \log n)$ , where  $n$  is the number of unique characters.

Complexity =  $O(n \lg n)$

# Application of Huffman Encoding

## Generic File Compression:

- ❖ Files: GZIP, BZIP, 7Z
- ❖ Archives : 7z
- ❖ File System : NTFS,FS+,ZFS

## Communication :

- ❖ ITU-T T4 Group 3 Fax
- ❖ V.42 Bis modem
- ❖ Skype

## Multimedia :

- ❖ Image : GIF, ZPEG
- ❖ Sound : Mp3
- ❖ Video : MPEG, HDTV

**Databases :** Google,Facebook,...

## Advantages :

- ➔The Huffman Coding has the minimum average length.
- ➔Easy to implement and fast.

## Disadvantages :

- ➔Requires two passes over the two input (one to compute frequencies, one for coding),thus encoding is slow.
- ➔Requires storing the Huffman codes(or at least character frequencies)in the encoded file, thus reducing the compression benefit obtained by encoding.

For example, let's take a case of 01111100,  
**Decoding**

| Character | Frequency | Code |
|-----------|-----------|------|
| a         | 12        | 0    |
| b         | 20        | 111  |
| c         | 5         | 1100 |
| d         | 10        | 1101 |
| e         | 11        | 100  |
| f         | 12        | 101  |

**Thus, we have decoded 01111100 into 'abc'.**

## Activity Selection Problem (Greedy Approach)

- **Activity Selection problem** is an approach of selecting non-conflicting tasks based on **start** and **end** time and can be solved in  $O(N \log N)$  time using a simple greedy approach.
- Modifications of this problem are complex and interesting which we will explore as well.
- With Dynamic Programming approach, the time complexity will be  $O(N^3)$  that is lower performance.

## Problem Statement

- **Activity Selection** is that "Given a set of  $n$  activities with their start and finish times, we need to select **maximum number of non-conflicting activities** that can be performed by a single person, given that the person can handle only one activity at a time."
- The Activity Selection problem follows **Greedy approach** i.e. at every step, we can make a choice that looks best at the moment to get the optimal solution of the complete problem.

# Objective

- Our objective is to complete maximum number of activities. So, choosing the activity which is going to finish first will leave us maximum time to adjust the later activities.
- This is the intuition that greedily choosing the activity with earliest finish time will give us an optimal solution.
- By induction on the number of choices made, making the greedy choice at every step produces an optimal solution, so we chose the activity which finishes first.
- If we sort elements based on their starting time, the activity with least starting time could take the maximum duration for completion, therefore we won't be able to maximise number of activities.

# Applications

- Scheduling events in a room having multiple competing events
- Scheduling and manufacturing multiple products having their time of production on the same machine
- Scheduling meetings in one room
- Several use cases in Operations Research

# Activity Selection Algorithm

```
Activity-Selection(Activity, start, finish)
    Sort Activity by finish times stored in finish
    Selected = {Activity[1]}
    n = Activity.length
    j = 1
    for i = 2 to n:
        if start[i] ≥ finish[j]:
            Selected = Selected U {Activity[i]}
            j = i
    return Selected
```

## Time Complexity:

- When activities are sorted by their finish time:  $O(N)$
- When activities are not sorted by their finish time, the time complexity is  $O(N \log N)$  due to complexity of sorting

# Example
